

TITLE OF THE INVENTION

CONTROL CONTENT TRANSMISSION METHOD AND STORAGE-BASED BROADCASTING SYSTEM

5 BACKGROUND OF THE INVENTION

Field of the Invention

The present invention relates to information service systems for automatically providing a user with a presenter required for viewing desired contents with a viewer regardless
10 of the presence or absence of a user's request and, more specifically, to a storage-based broadcasting system that automatically updates the viewer.

Description of the Background Art

15 Information service systems for providing users with a service for viewing contents require a browser for supplying the content data to a presenter to make them available to the user. This browser must be appropriately updated depending on factors attributed to content data to be provided, a transmission channel
20 used for providing the content data to the user, and the presenter on the user's side.

As one example of conventional information service systems, a push-type information distribution service using a computer over the Internet has been realized by, for example, PointCast
25 Network (registered trademark) of PointCast Incorporated, and

Active Desktop (registered trademark) of Microsoft Corporation.

In such push-type information distribution service, contents such as news and weather forecast that are broadcast from a broadcast station over the Internet are received by and stored
5 in a receiver such as a personal computer. A user operates the receiver to activate a browser, which is a user interface for viewing contents. Thus, the user can view the contents stored in the receiver.

Different browsers are used for different services.
10 Consequently, a flexible user interface can be achieved for each service. If the browser needs to be updated, the user receives a new browser by using a function programmed directly on the current browser itself. Then, the current browser is replaced with the received new browser. In this way, the browser can be
15 updated.

With reference to FIGS. 24, 25, 26, 27, 28, 29, and 30, one example of the conventional broadcasting system is now described. As shown in a block diagram of FIG. 24, a broadcasting system 2500 includes a transmitting apparatus 2510, a delivery system 120,
20 and a receiving apparatus 2520. The transmitting apparatus 2510 includes browser storages 2511, browser pitchers 2513, content storages 1113, content pitchers 2514, a multiplexer 115, and a transmitter 116.

There are two or more browser storages 2511, browser
25 pitchers 2513, content storages 1113, and content pitchers 2514

provided. Each of these components is given a symbol with a suffix (lower-case alphabet) added thereto. Hereinafter, the same components are each given the same symbol with a different suffix added thereto for identification.

5 In the example of FIG. 24, three browser storages 2511 are provided: browser storages 2511a, 2511b, and 2511c; three browser pitchers 2513 are provided: browser pitchers 2513a, 2513b, and 2513c; three content storages 1113 are provided: contents storages 1113a, 1113b, and 1113c; and three content
10 pitchers 2514 are provided: content pitchers 2514a, 2514b, and 2514c. Note that, if each of the same components needs not specifically to be identified, they are generally referred to as the browser storages 2511, the browser pitchers 2513, the content storages 1113, the content pitchers 2514, respectively.

15 In this specification, if there are a plurality of the same components as describe above, they are identified by adding a suffix to each symbol. Furthermore, if each of them needs not specifically to be identified, they are generally referred to without a suffix added to the symbol.

20 In FIGS. 25, 26, 27 and 28, data stored in the browser storages 2513, the content storages 2513, the storage 133, and the memory 138 in the above broadcasting system 2500 are shown. The three browser storages 2511a, 2511b, and 2511c are independently and respectively provided for three service (S1,
25 S2, and S3). The browser pitchers 2513 each store a browser B

that corresponds to a service (S) to be provided to a user, and send the browser B to the multiplexer 115 according to a predetermined schedule.

The browser pitcher 2513a for the service S1 stores a browser B(S1). The browser B is a computer program written in native code (machine language) of a CPU (Central Processing Unit) in the receiving apparatus 2520. Similarly, the browser 2513b for the service S2 stores a browser B(S2), and the browser 2513c for the service S3 stores a browser B(S3). Note that if each of them needs not specifically to be identified, they are simply referred to as the browser B.

A specific browser transmission technique such as a communication protocol and transmission schedule is defined for each service. Thus, processes carried out by the browser pitchers 2513 vary among the services. For this reason, the browser pitchers 2513a, 2513b, ..., 2513n (n is an arbitrary natural number) are independently and respectively provided for the services.

In the example shown in FIG. 24, the three browser pitchers 2513a, 2513b, and 2513c are independently provided for the three services S1, S2, and S3, respectively. The content storage 1113 stores a content C of the corresponding service. The content storage 1113 is provided for each service. In FIG. 25, the three content storages 1113a, 1113b, and 1113c are independently provided for the three service, respectively.

In the example shown in FIG. 25, the content storage 1113a for the service S1 stores two service contents C(S1, 1) and C(S1, 2). The content storage 1113b for the service S2 does not store any content C. The content storage 1113c for the service S3 stores
5 three service contents C(S3, 1), C(S3, 2), and C(S3, 3). Note that if each of the contents needs not specifically to be identified, the content is simply referred to as the service content C.

Referring back to FIG. 24, the content pitcher 2514 sends
10 the content C(Sm, O) stored in the content storage 1113 of the corresponding service to the multiplexer 115 in a predetermined manner. In the content C(Sm, O), Sm represents a service S with a suffix m (m is an arbitrary natural number) for identification, and O (O is an arbitrary natural number) represents an ordinal
15 number of a plurality of contents C that form the service Sm.

As such, in the transmitting apparatus 2510 used for the conventional broadcasting system 2500, methods for transmitting browsers and contents vary among services. Therefore, the plurality of browser pitchers 2513 and content pitchers 2514 have
20 to be individually provided for the services. Moreover, different transmission methods should be respectively prepared for the browser B and the content C. Therefore, the plurality of pitchers have to be individually provided for the browser B and the content C.

25 The multiplexer 115 multiplexes and modulates the browser

B received from the browser pitcher 2513 and the service content C (Sm, O) received from the content pitcher 113 to output a digital bit stream. The multiplexer 115 may be structured by a multiplexer and a modulator in a station system for digital
5 broadcasting.

The transmitter 116 sends data processed by the multiplexer 115 to the delivery system 120. The transmitter 116 may be implemented by a modem if the delivery system is structured by a wired communications circuit, or may be implemented by a
10 parabolic antenna for transmission if structured by a broadcasting communications satellite in space.

The delivery system 120 is now described. The delivery system 120 is a means for transmitting information, such as contents and browsers sent from the transmitting apparatus 2510,
15 to the receiving apparatus 2520. For example, the delivery system 120 may be structured by an optical fiber or cables of various types; a broadcasting communications satellite in space; or a package medium such as a DVD and its distribution channels.

The receiving apparatus 2520 is now described in detail.
20 The receiving apparatus 2520 includes a receiver 131, a demultiplexer 132, a storage 133, a renderer 134, a presenter 135, an input device 136, a CPU 137, and memory 138.

The receiver 131 receives information such as the content C and the browser B through the delivery system 120 to output a
25 digital bit stream. The receiver 131 may be implemented by a modem,

or a module including an antenna and a tuner that are used in general digital broadcasting receivers.

The de-multiplexer 132 demodulates the digital bit stream received from the receiver 131, and separates the multiplexed information. That is, the de-multiplexer 132 carries out the process carried out by the multiplexer 115 of the transmitting apparatus 2510 in the reverse direction. An output from the de-multiplexer 132 is provided to the storage 133 and can be read by the CPU 137.

The storage 133 stores the browsers and contents provided by the de-multiplexer 132. The storage 133 is implemented by, for example, a randomly-accessible recording medium such as a hard disk. Information stored in the storage 133 is readable and changeable by the CPU 137.

As illustrated in FIG. 26, the storage 133 stores the three browsers B(S1), B(S2), and B(S3), and five contents C(S1, 1), C(S1, 2), C(S3, 1), C(S3, 2), and C(S3, 3).

The renderer 134, by following an instruction from the CPU 137, renders graphics for displaying on-screen display (OSD) on a screen.

The presenter 135 presents an output of the renderer 134 as viewable for the user. The presenter 135 may be implemented by a CRT display, for example.

The input device 136 is operated by the user to instruct the receiving apparatus 2520. The input device 136 may be

implemented by a combination of a remote controller and its photoreceptor, a keyboard, a mouse, or others.

The CPU 137, which is a central processing unit, is interconnected to each component of the receiving apparatus 2520. By executing a computer program stored in the memory 138, the CPU 137 controls the entire receiving apparatus 2520.

The memory 138 is constructed of a writable/unwritable semiconductor memory RAM/ROM. The memory 138 is used for storing data processed by the CPU 137 and for storing a computer program and data to be executed in the CPU 137. As illustrated in FIG. 27, the memory 138 stores a browser list 2700, and a computer program 2651 written in native code (machine language) executable by the CPU 137.

With reference to FIG. 28, the browser list 2700 is now described. The browser list 2700 indicates information in a tabular form with rows for the services. The browser list 2700 includes a column 2710 for browser file names and a column 2520 for service names. With the use of the browser list 2700, the browser can be specified for a desired service from among information stored in the storage 133.

With reference to a flow chart in FIG. 29, the main operation of the receiving apparatus 2520 is now described in detail.

In step S2801, all service names (2720) of the browser list 2700 stored in the memory 138 are displayed on the screen in list form. Such screen display is carried out by the renderer 134.

In step S2802, the user operates the input device 136 to select one of the services in the list displayed in step S2801.

In step S2803, for the service selected in step S2802, the file name B(Sm) stored in the storage 133 is obtained by referring
5 to the browser-file-name column in the browser list 2700.

In step S2804, the file B(Sm) specified in step S2803 is executed. The browser is written in native code of the CPU 137, and therefore can be executed directly by the CPU 137.

With reference to a flow chart in FIG. 30, a browser updating
10 process by the receiving apparatus 2520 is now described.

In step S2901, the CPU 137 starts executing the currently-transmitted browser B.

In step S2902, the browser B is received by the receiver 131 and then the de-multiplexer 132, and its version is checked.

15 In step S2903, if the browser B received in step S2902 is a new version of the currently-executed browser B, the procedure goes to a next step S2904, and if not, the procedure ends.

In step S2904, the receiver apparatus 2520 receives the currently-transmitted browser B, and the storage 133 temporarily
20 stores the received browser B as a file.

In step S2905, the currently-executed browser B is replaced with the temporarily-stored file. Then, by rebooting the browser B, the received browser of the new version starts to be executed.

In the above example of the conventional broadcasting
25 system, the browser written in native code of the computer is

transmitted by using a method unique to each service. Therefore, various browser transmission methods specific to services have to be incorporated in both transmitting and receiving apparatuses.

5 That is, in the transmitting apparatus, various browser pitchers specific to services are required. In the receiving apparatus, a function is programmed, typically in the browser code for each service, for receiving a new browser for a new service and replacing the existing browser with the received new browser.

10 To realize substantially the same function for each service, the browsers each should be implemented in slightly different specification.

 Therefore, as the number of services increases, various needlessness occurs. That is, in the receiving apparatus, a
15 plurality of similar program codes have to be held, thereby wasting the storage capacity. Also, similar processes are simultaneously activated in the receiving apparatus, and therefore computer resources cannot be efficiently used.

 Furthermore, browser transmission methods vary among the
20 services, and are programmed only in the browsers. Therefore, the user suffers inconvenience of manually obtaining the browser in advance by activating a file communications protocol such as ftp.

 Still further, there are various differences between the
25 browser and the content in transmission method. Therefore, in

a case where a plurality of services are subscribed, transmission of one service may interfere with transmission of another browser or service.

Also in the transmitting apparatus, slightly different
5 browser pitchers are required as many as the services in order to achieve browser transmission, which is essentially the same function to any service. Therefore, the transmitting apparatus becomes more complicated in structure linearly as the number of services increases. This complicated structure causes an
10 increase in development cost and inconvenience in management.

Furthermore, these browser pitchers have no relation to one another. These browser pitchers may transmit browsers more than the delivery system can handle, causing an overflow. The content pitchers are also independent of one another for each service,
15 and therefore the same problem may occur.

SUMMARY OF THE INVENTION

An object of the present invention is to provide a method and system for providing a flexible user interface for services
20 in storage-based broadcasting in which service structured by a plurality of contents transmitted in digital broadcasting or a computer network, while securing services from invalid or unauthorized contents.

The present invention has the following features to solve
25 the problem above.

A first aspect of the present invention is directed to a storage-based broadcasting system that supplies a user interface unique to a service composed of a content stored therein for presenting the service, the service comprising:

5 a transmission unit for transmitting a control content for realizing the user interface as entire or part of the content; and

 a receiving unit for receiving and activating the transmitted control content to execute the user interface,
10 wherein

 the user interface is transmitted and received as a content. According to a second aspect, in the first aspect, the control content is a browser for the stored content. According to a third aspect, in the first aspect,

15 the transmitting apparatus comprises:

 content pitcher means for pitching the content including the control content; and

 a service property transmitting unit for transmitting service property information indicating the service, and

20 the receiving unit comprises a control content determination unit for determining, based on the received content and service property information, the control content among the received contents.

 According to a fourth aspect, in the third aspect,
25 the content pitcher unit comprises a content assembler unit

for adding, to the content, a content header defining the content,
and

the receiving unit further determines the control content
among the received contents based on the content header of the
5 received content.

According to a fifth aspect, in the third aspect,

the transmitting unit further comprises an electronic
signature unit for placing an electronic signature on the control
content, and the service property transmitting unit transmits a
10 public key of the electronic signature as being included in the
service property information, and

the receiving unit further comprises a signature
authentication unit for authenticating the electronic signature
by a public key included in the received service property
15 information, and the control content is determined through
authentication of the electronic signature.

According to a sixth aspect, in the fifth aspect,

the authentication of the electronic signature is performed
using a key unique to the service.

20 According to a seventh aspect, in the third aspect,

the content pitcher unit further comprises a content ID
space management unit for sending information for defining part
of ID space of the content, and

the receiving unit further comprises a designation unit for
25 designating the control content based on the content ID included

in the part of ID space.

An eighth aspect of the present invention is directed to, in a storage-based broadcasting system that supplies a user interface unique to a service (S) composed of a content (C) stored therein for presenting the service, a control content transmission method for providing a user interface unique to each of the services, the method comprising:

a step of transmitting a control content for realizing the user interface as entire or part of the content; and

a step of receiving and activating the transmitted control content to execute the user interface.

According to a ninth aspect, in the eighth aspect, the control content is a browser for the stored content.

According to a tenth aspect, in the eighth aspect, the transmitting step comprises:

a step of pitching the content including the control content; and

a step of transmitting service property information indicating the service, and

the receiving step comprises a step of determining the control content among the received contents based on the received content and service property information.

According to an eleventh aspect, in the tenth aspect, the content sending step comprises a step of adding, to the

content, a content header defining the content, and

the receiving step further comprises a step of determining, based on the content header of the received content, the control content among the received contents.

5 According to a twelfth aspect, in the tenth aspect, the transmitting step comprises a step for placing an electronic signature on the control content,

the service property transmitting step further comprises a step of transmitting a public key of the electronic signature as being included in the service property information, and

10 the receiving step further comprises:

a step of authenticating the electronic signature by a public key included in the received service property information; and

15 a step of determining the control content through authentication of the electronic signature.

According to a thirteenth aspect, in the twelfth aspect, the authentication of the electronic signature is performed using a key unique to the service.

20 According to a fourteenth aspect, in the tenth aspect, the content pitching step further comprises a step of sending information for defining part of ID space of the content, and

the receiving step further comprises a step of determining the control content based on the content ID included in the part

of ID space.

These and other objects, features, aspects and advantages of the present invention will become more apparent from the following detailed description of the present invention when
5 taken in conjunction with the accompanying drawings.

10 DESCRIPTION OF THE PREFERRED EMBODIMENTS

(First embodiment)

With reference to FIGS. 1, 2, 3, 4, 5, 6, 7, 8, 9, and 10, a storage-based broadcasting system according to a first embodiment of the present invention is described.

15 As shown in FIG. 1, a storage-based broadcasting system 100 according to the first embodiment includes a transmitting apparatus 110, a delivery system 120, and a receiving apparatus 130.

The transmitting apparatus 110 includes a service property
20 storage 111, a content assembler 112, content body storages 113, a content body pitcher 114, a multiplexer 115, and a transmitter 116. There are two or more content body storages 113 provided. Each of these components is given a symbol with a suffix (lower-case alphabet) added thereto for identification.
25 Similarly, hereinafter in the specification, the same components

are each given a symbol with a suffix for identification. If each of the same components needs not specifically to be identified, they are generally referred to with the symbol only and no suffix, such as the content body storages 113.

5 Each content body storage 113 stores a content body Dc, which is substance data of each service. Each content body storage 113 provides the content body Dc to the content body pitcher 114.

10 The content body pitcher 114 sends, or pitches, the provided content body Dc to the content assembler 112.

15 The content assembler 112 produces a content header Hc and the like with reference to service property information stored in the service property storage 111. Then, the content assembler 112 assembles the received content body Dc, the content header Hc, and the like into a content C. The content body Dc is composed of management information of the content body Dc including header information to generate a content C. This generated, or assembled, content C is provided to the multiplexer 115.

20 The multiplexer 115 multiplexes the service property information Isp received from the service property storage 111 and the content C received from the content assembler 112. The multiplexer 115 then provides the multiplexed information to the transmitter 116.

25 The transmitter 116 modulates the multiplexed service property information Isp and the content C into a digital bit

stream in a form suitable to the delivery system, and then outputs the modulated information to the delivery system 120. The transmitter 116 may be implemented by a modem if the delivery system is structured by a wired communications circuit, or may
5 be implemented by a parabolic antenna for transmission if structured by a broadcasting communications satellite in space.

The delivery system 120 is a means for transmitting information such as a content C and a browser B sent from the transmitting apparatus 110 to the receiving apparatus 130. For
10 example, the delivery system 120 may be structured by an optical fiber or cables of various types; a broadcasting communications satellite in space; or a package medium such as a DVD and its distribution channels.

The receiving apparatus 130 includes a receiver 131, a
15 de-multiplexer 132, a storage 133, a renderer 134, a presenter 135, an input device 136, a CPU 137, and memory 138. Note that the storage 133, the renderer 134, the input device 136, the CPU 137, and the memory 138 are connected to one another through a data bus.

20 The receiver 131 receives the content C and the browser B through the delivery system 120, and outputs a digital bit stream. The receiver 131 may be implemented by a communications modem, a cable modem, a mobile communications module such as Bluetooth, or a module including an antenna and a tuner that are used in
25 general digital broadcasting receivers.

The de-multiplexer 132 demodulates the digital bit stream received from the receiver 131, and separates the multiplexed information. That is, the de-multiplexer 132 carries out the process carried out by the multiplexer 115 of the transmitting apparatus 110 in the reverse direction. An output from the de-multiplexer 132 is provided to the storage 133 and can be read by the CPU 137.

The storage 133 is, for example, a randomly-accessible recording medium such as a hard disk, and readable and changeable by the CPU 137. The storage 133 stores a service content $C(Sm, 0)$ and a browser content $(Sm, Bflg)$ received from the de-multiplexer 132. The service content $C(Sm, 0)$ is a service substance such as a broadcast program or data provided by the storage-based broadcasting system 100 and viewed with enjoyment or used by users. The browser content $C(Sm, Bflg)$ realizes a user interface for the user to enjoy and use the provided service on the receiving apparatus 130. The browser content $C(Sm, Bflg)$ is control code executable under a program code execution environment provided by the receiving apparatus 130, and targets the service content $C(Sm, 0)$ for processing.

The renderer 134, by following an instruction from the CPU 137, renders graphics for displaying on-screen display (OSD) on a screen.

The presenter 135 presents an output of the renderer 134 as viewable for the user. The presenter 135 may be implemented

by a CRT display, for example.

The input device 136 is operated by the user to instruct the receiving apparatus 130. The input device 136 may be implemented by a combination of a remote controller and its photoreceptor, a keyboard, a mouse, or other components.

The CPU 137, which is a central processing unit, is interconnected to each component of the receiving apparatus 130. By executing a computer program stored in the memory 138, the CPU 137 controls the entire receiving apparatus 130.

10 The memory 138 is constructed of a writable/unwritable semiconductor memory RAM/ROM. The memory 138 is used for storing data processed by the CPU 137 and for storing a computer program and data to be executed in the CPU 137.

In FIGS. 2, 3, 4 and 5, the states of data stored in each component of the storage-based broadcasting system 100 are shown.

As shown in FIG. 2, the service property storage 111 is provided for storing the service property information Isp indicating a property of each service to be provided by the storage-based broadcasting system 100.

20 As shown in FIG. 3, the content body storage 113 stores a content body Dc, which is a substance of the content C composing each corresponding service. The content body storage 113 is provided for each service. That is, three content body storages 113a, 113b, and 113c are independently provided for three
25 difference service. The content body storage 113a corresponds

to a service $S1$, storing two content body $Dc(S1, 1)$ and $Dc(S1, 2)$ and one browser content body $Dc(S1, Bflg)$. An arbitrary content body Dc is hereinafter represented as a content body $Dc(Sm, 0)$, where a symbol S with a suffix m (m is an arbitrary natural number) indicates each service for identification, and a parameter 0 (0 is an arbitrary natural number) indicates an ordinal position of the content body in the contents C that compose a service Sm . The browser content body $Dc(S1, Bflg)$ is generated from a browser $B(S1)$ for the service $S1$ in the same format as the content body Dc , and can be generally referred to as a browser content body $Dc(Sm, Bflg)$, like the service content body $Dc(Sm, 0)$.

On the other hand, unlike the service content body $Dc(Sm, 0)$, the browser content body $Dc(Sm, Bflg)$ includes a parameter $Bflg$ indicating the service property information Isp , instead of the parameter 0 . The service property information Isp will be described later referring to FIG. 4. However, the browser content body $Dc(Sm, Bflg)$ are the same in data format as the service content body $Dc(Sm, 0)$. Therefore, the content body storage 113 cannot discriminate therebetween, and handles both as the content body Dc . In this meaning, the browser content body $Dc(Sm, Bflg)$ and the service content body $Dc(Sm, 0)$ are collectively referred to the content body Dc .

Hereinafter, for simplification, the service content body $Dc(Sm, 0)$ is abbreviated as a service content body DcS , and the

browser content body $Dc(Sm, Bflg)$ is as a browser content body DcB , as required. Furthermore, the browser content $C(Sm, Bflg)$ composed of the browser content body $Dc(Sm, Bflg)$ is abbreviated as a browser content Cb , and the service content $C(Sm, 0)$ composed of the service content body $Dc(Sm, 0)$ as a service content Cs .

With reference to FIG. 4, 5, and 6, the service content Cs and the browser content Cb outputted from the content assembler 112 are described in detail. In FIG. 4, the service property information Isp stored in the service property storage 111 is exemplarily shown. The service property information Isp relates to all services ($S1, S2, S3, \dots, Sm$) to be provided by the storage-based broadcasting system 100. In a table shown in FIG. 3, each row corresponds to each service, and is composed of a service ID and service name.

For example, in the first row, a service with its service ID "S1" and service name "Today's News" is shown. Similarly, a service with its service ID "S2" and service name "Useful Information" is shown in the second row, and a service with its service ID "S3" and service name "New Car Guide" in the third row. The service ID is unique to each service in the service property information Isp , and can be used for identifying each service.

In FIG. 5, the data structure of the service content Cs is schematically shown. In FIG. 6, the data structure of the browser content Cb is schematically shown. The content C is structured of the content body Dc , which is data of the content C itself,

and the content header Hc, which is meta data accompanying the content body Dc.

In FIG. 5, the service content body DcS of the content C(S1, 1) of the service content Cs is related to the content header HcS.

5 In FIG. 6, the browser content body DcB of the content C(S1, Bflg) of the browser content Cb is related to the content header HcB.

The content header Hc (HcS and HcB) are represented in tabular form taking a set of an item and a value as one row. The content header HcS includes four rows: the service ID, content
10 ID, content version, and content name.

The service ID corresponds to the service ID of the service property information Isp illustrated in FIG. 4. The service ID identifies the service S to which the content C corresponds. In the present example, the service ID is "S1", and therefore
15 indicates that the content C is the service "Today's News" as shown in FIG. 4.

The content ID is used for identifying the content C itself. Thus, each content ID takes a unique value in the storage-based broadcasting system 100.

20 The content version is provided for indicating whether the version of the content C is older or newer compared with other content C. Each content ID has a value of the content version independently of one another. When the content Cc currently stored in the storage 133 (as will be described later with
25 reference to FIG. 7 is replaced with the new content Cn for update,

a content version larger in number than the current content Cc is provided to the new content Cn.

The content name is an item for the user to select as a character string. In the present example, the content name indicates that the content body Dc is "Weather Forecast".

The above-stated service ID, content ID, content version, and content name are included in both of the service content header HcS and the browser content header HcB.

However, as shown in FIG. 6, the browser content header HcB of the browser content Cb further includes a row indicating a browser content flag.

The browser content flag is an item for indicating that the content C is the browser content Cb, and is equivalent to Bflg as stated above. The browser content flag in the browser content header HcB is True, thereby indicating that the content body Dc is the browser content body DcB.

In the browser content Cb as shown in FIG. 6, the service ID is "S1", and the content ID is "101". That indicates that the browser content Cb for the service "Today's News" is composed of the content body Dc with the content ID "101". In other words, at least three items, that is, the service ID, content ID, and browser content flag, are required to define the content C as the browser content Cb.

The process carried out by the service property storage 111, the content assembler 112, the content body storages 113, and the

content body pitcher 114 is described below based on the data structure of the content C as described above.

5 The content body pitcher 114 sends, or pitches, the content bodies Dc successively and repeatedly provided by the content body storages 113 to the content assembler 112. The content assembler 112 adds a content header (HcS, HcB) to the content body Dc (DcS, DcB) to generate the content C (Cs, Cb) for output to the multiplexer 115.

10 With reference to FIGS. 7 and 8, description is now made of data form in which the content C (service content Cs, browser content Cb) transmitted from the transmitting apparatus 110 through the delivery system 120 is stored in each component of the receiving apparatus 130.

15 The transmitting apparatus 110 sends to the delivery system 120 a digital bit stream composed of the content C and the service property information Isp. The digital bit stream is first received by the receiver 131 of the receiving apparatus 130, and then provided to the de-multiplexer 132.

20 The de-multiplexer 132 demodulates the digital bit stream into the content C and the service property information Isp for reproduction. The de-multiplexer 132 further extracts the content header Hc from the reproduced the content C, and outputs the extracted content header Hc and the service property information Isp to the bus.

25 On the other hand, the reproduced content C is temporarily

held in the de-multiplexer 132. For discriminating between the reproduced content C and the content C already stored in the storage 133, the former is hereinafter referred to as a demodulated content Cn, and the latter is as a stored content Cc.

5 The storage 133 receives, in predetermined timing, the content C reproduced by the de-multiplexer 132, and stores the received the content C therein. As shown in FIG. 7, the contents C (Cs, Cb) for the services outputted from the content assembler 112 to the multiplexer 115 are stored in the storage 133.

10 That is, eight contents produced of eight content bodies in the content body storage 113a, 113b and 113c are stored in the storage 133. Specifically speaking, the content C(S1, Bflg) is produced of the content body Dc(S1, Bflg), the content C(S1, 1) is produced of the content body Dc(S1, 1), the content C(S1, 2) of the content body Dc(S1, 2); the content C(S2, Bflg) of the
15 content body Dc(S2, Bflg); and the content C(S3, Bflg) of the content body Dc(S3, Bflg), the content C(S3, 1) of the content body Dc(S3, 1), the content C (S3, 2) of the content body Dc(S3, 2), and the content C(S3, 3) of the content body Dc(S3, 3) are
20 stored in the storage 133.

The storage 133 also sends various data, typified by the content body Dc included in the stored content C, to the bus and the renderer 134 under the control of the CPU 137.

The renderer 134 generates, based on the received
25 information, a video signal for rendering an image on the

presenter 135.

As shown in FIG. 8, the memory 138 stores the service property information Isp, a browser content executer 271, and a computer program 2651, which is native code for the CPU 137. The browser content executer 271 is to execute the content as a high-level language computer program.

With reference to a flow chart shown in FIG. 9, the operation of activating the browser content Cb included in the content C received by the receiving apparatus 130 is described.

10 In step S501, the service names of the services described in the service property information Isp outputted from the de-multiplexer 132 are presented in list form on a display of the presenter 135.

15 In step S502, the user operates the input device 136 to select one of the services by referring to the service name list displayed in step S501. Based on the selection by the user through the input device 136 and the service name list, the service selected by the user is determined.

20 In step S503, the service ID that corresponds to the service determined in step S502 is obtained based on the service property information Isp.

In step S504, all contents C stored in the storage 133 are searched for the content Cb having the same service ID as that obtained in step S503 and whose browser content flag is True.

25 In step S505, the browser content Cb found in step S504 is

provided to the browser content executer 271 for execution.

As such, the browser content flag is provided to the content header HcB of the browser content Cb. With the browser content flag, the browser content Cb and other service content Cs can be discriminated. Furthermore, once each service S is specified, the browser content Cb (C(Sm, Bflg)) corresponding thereto can be activated as a browser.

With reference to a flow chart shown in FIG. 10, the operation of storing and updating the content by the receiving apparatus 130 is now described.

In step S601, the content Cn (Cb, Cs), the service property information Isp, and the content header Hc (HcB, HcS) are reproduced by the de-multiplexer 132.

In step S602, the content header Hc reproduced in step S601 is outputted to the bus.

In step S603, the storage 133 is searched for the current content Cc that corresponds to the reproduced content header Hc for selection. That is, among all contents C stored in the storage 133, the current content Cc having the same content ID as that described in the reproduced content header Hc is selected.

In step S604, if it is determined in step S603 that there is no such current content Cc having the same content ID in the storage 133, the procedure goes to step S605.

In step S605, the demodulated new content Cn is outputted to the storage 133, and newly stored therein. The procedure then

returns to step S601.

On the other hand, in step S604, if it is determined in step S604 that there is any current content Cc having the same content ID in the storage 133, the procedure goes to step S606.

5 In step S606, based on the reproduced content header Hc, the new content Cn held in the de-multiplexer 132 is compared, in content version, with the current content Cc found in step S603. If the demodulated new content Cn is newer than the current content Cc, the procedure goes to step S607.

10 In step S607, the current content Cc stored in the storage 133 is replaced with the new content Cn held in the de-multiplexer 132. With this replacement, the current content Cc is updated to the new content Cn. At the time when the update is completed, the new content Cn is dealt with as "current content Cc". Then,
15 the procedure returns to step S601.

On the other hand, if it is determined in step S606 that the demodulated new content Cn is not newer than the current content Cc stored in the storage 133, the step of updating the content C (step S601) is skipped, and the procedure returns to
20 step S601.

As described above, in the storage-based broadcasting system 100, the transmitting apparatus 110 sends the browser content Cb for providing a user interface with each service Sm as the whole or part of the contents C composing each service Sm.
25 Then, the receiving apparatus 130 receives the transmitted

content C, and activates the browser content Cb included in the received content C to execute the user interface.

The process of updating the content C is carried out irrespectively of the type of the content C, that is, the service content Cs or the browser content Cb. This updating function is not for a specific service, but for all services in common. Therefore, only with this content-updating function being achieved, the service contents Cs and the browser contents Cb for all services can be updated and stored in the receiving apparatus 130.

In other words, in this embodiment, the browser content Cb, which is a user interface with a service, is sent as part of the content. Therefore, an additional function for transmitting the user interface for the service is not required. Also, updating the content also can make the user interface updated.

(Second embodiment)

With reference to FIGS. 11, 12, 13, and 14, a storage-based broadcasting system according to a second embodiment of the present invention is described below. As shown in FIG. 11, similarly to the storage-based broadcasting system 100 shown in FIG.1, a storage-based broadcasting system 700 according to this embodiment includes a transmitting apparatus 710, a delivery system 120, and a receiving apparatus 730.

The transmitting apparatus 710 is the same in structure as the transmitting apparatus 110 of the storage-based broadcasting

system 100 with a signature generator 711 added thereto. The receiving apparatus 730 is the same in structure as the receiving apparatus 130 with a KP extractor 740, an Sg extractor 741, and a decryptor 721 added thereto. Therefore, only the unique
5 features of the storage-based broadcasting system 700 are described below.

The signature generator 711 manages keys for electronic signature and also places an electronic signature (digital signature) to the browser content Cb. For electronic signature,
10 a public key encryption technique is used. In this technique, a set of a secret key and a public key are generated in an information provider. Only the public key is given to an information user, and the secret key is held secret. Using the given secret key, the information provider places an electronic
15 signature on information to be provided (the information with the electronic signature takes a form of a set of original information and the electronic signature). Using the information with the electronic signature and the public key received from the signature, the user can authenticate that the received
20 information is the one with the electronic signature placed by the information provider having the secret key.

Here, the signature generator 711 holds a secret key and a public key for each service. The signature generator 711 places an electronic signature on the browser content Cb of the service
25 using the secret key for the service. That is, the signature

generator 711 is connected to each of the content storages 113a, 113b, and 113c. Based on the services of the content bodies Dc received therefrom, the signature generator 711 outputs a public key KP varied among the services to the service property storage
5 111.

Specifically, as shown in FIG. 13, a signature item is added to the content header HcB of the browser content Cb. Thus, the electronic signature is stored in the browser content Cb. That is, the content header of the browser content Cbc(S1, Bsgn)
10 includes a row for electronic signature. Stored in the "Value" column corresponding to the "Signature" row is information that resulted from the electronic signature placed on the corresponding content body Dc with a secret key for the service of the content.

15 Hereinafter, the content header HcB with the electric signature added thereto is referred to as a content header HcBc. The browser content having the "Signature" item is referred to as a browser content Cbc for discrimination from other browser contents Cb, and also represented as C(Sm, Bsgn).

20 The service property storage 111 generates service property information Ispc including the public keys KP, and outputs the generated information to the multiplexer 115. In FIG. 12, the structure of the generated service property information Ispc is shown. The service property information Ispc is given a column
25 for storing a value of the public keys KP. One public key is stored

for each of the services S1, S2, and S3.

The signature generator 711 generates and outputs an electronic signature Sg to the content assembler 112. Based on the content body Dc provided by the content body pitcher 114 and the electronic signature Sg provided by the signature generator 711, the content assembler 112 generates the browser content Cbc with the signature. The content assembler 112 then outputs the browser content Cbc and the service content Cs collectively as the content C to the multiplexer 115.

10 The receiving apparatus 730 reproduces the content C (Cs and Cbc), the content header Hc (HcS, HcBc), and the service property information Ispc from a digital bit stream received by the de-multiplexer 132. The content C (Cs, HcBc) is held in the de-multiplexer 132. The content header Hc (HcS, HcBc) is 15 outputted to the bus and the Sg extractor 741. The service property information Ispc is outputted to the KP extractor 740.

The Sg extractor 741 extracts the electronic signature Sg from the content header HcBc of the reproduced browser content C(Sm, Bsgn), and outputs the extracted signature Sg to the bus.

20 The KP extractor 740 extracts the public key KP from the service property information Ispc, and outputs the extracted public key KP to the bus.

The decryptor 721 authenticates the electronic signature in the content header HcBc based on the public key KP provided 25 through the bus.

As stated above, in the receiving apparatus 730, the browser content Cbc can be authenticated by the electronic signature Sg of the received browser content Cbc and the public key KP in the service property information Ispc. In other words, it can be
5 ensured that the browser content Cbc has been encrypted with the secret key unique to the service by a service content creator.

The operation of the receiving apparatus 720 according to this embodiment is now described. With reference to a flow chart shown in FIG. 14, the process of activating the browser content
10 Cb by the receiving apparatus 730 in the storage-based broadcasting system 700 is described.

Here, the process in steps S501c, S502, S503c and S504 is basically the same as that in step S501, S502, S503, and S504 in the above-stated receiving apparatus 130 except that the service
15 property information Isp is replaced with the service property information Ispc and that the content C to be processed is replaced with the browser content Cbc. Therefore, description of the same process is omitted herein.

In step S1001, the "Signature" row of the content header
20 of the extracted browser content Cbc is referred to. If the signature row is not available, that is, if the browser content Cbc with signature is abnormal, the procedure goes to step S1004.

In step S1004, a warning that the browser content Cbc with signature is abnormal is displayed, and the procedure ends.

25 On the other hand, if the signature row is available, the

procedure goes to step S1002.

In step S1002, it is authenticated whether the electronic signature Sg in the browser content Cbc is placed with the secret key that corresponds to the public key KP. The public key KP for use in this authentication is obtained by selecting the row
5 corresponding to the service from the service property information Ispc.

In step S1003, if it is determined in step S1002 that the electronic signature Sg is not appropriate, the procedure goes
10 to step S1004.

In step S505c, the browser content Cbc with an appropriate electronic signature is executed by the browser content executor. Then, the procedure ends.

In step S1004, a warning that browser content Cb is invalid
15 because it has no signature or erroneous one is given. Then, the procedure ends.

As stated above, in the second embodiment, with the electronic signature technique, only the person who owns the public key to a target service can send the browser content Cb
20 executable in the receiving apparatus 720.

Therefore, if a person who does not own the public key for the target service stores any content in the content body storage, the erroneous browser content Cb can be prevented from being intentionally sent and executed in the receiving apparatus 730.
25 Moreover, the browser content Cb with an electronic signature with

a secret key for another service can be prohibited from being executed as the browser content Cb for the target service.

In this embodiment, the electronic signature is placed only on the content body. However, the content header may be included
5 in the content body to carry the electronic signature.

Note that a simple electronic signature technique without using public key encryption may be used. For example, one secret key for each service is created, and stored in the receiving apparatus in a predetermined manner. Then, information
10 indicative of the browser content Cb is encrypted with the secret key for each service and decrypted in the receiving apparatus side with the secret key, thereby determining the browser content Cb.

As stated above, in this embodiment, the signature generator 711 places an electronic signature on the browser
15 content Cbc, which provides a user interface with the service. The content body storages 113 each send the content body Dc including the browser content body DcBc. The service property storage 111 sends the public key KP for the electronic signature Sg as the service property information Ispc for all services in
20 common. The receiving apparatus 730 authenticates the electronic signal Sg to determine that the content C is the browser content Cbc. With these components provided to the storage-based broadcasting system 700, reliability of the content C distributed therein can be ensured.

25 That is, in this embodiment, the electronic signature

technique is used for designating the browser content Cb among a plurality of contents C composing a single service. The key for use in electronic signature is provided for each service provider. Thus, the browser content Cb for the service cannot
5 be designated by anyone other than the service provider. Consequently, the browser content Cb is prevented from being willfully designated by anyone other than the service provider without proper authorization.

(Third embodiment)

10 With reference to FIGS. 15, 16, 17, and 18, a storage-based broadcasting system according to a third embodiment of the present invention is now described. As shown in FIG. 15, a storage-based broadcasting system 1000 according to this embodiment includes a transmitting apparatus 1010, a delivery system 120, and a
15 receiving apparatus 130, as in the storage-based broadcasting system 100 shown in FIG. 1. The transmitting apparatus 1010 is similar in structure to the transmitting apparatus 110 of the storage-type broadcasting system 100 except that the content assembler 112 of the transmitting apparatus 110 in the
20 storage-based broadcasting system 100 is replaced with a content assembler 112i. Therefore, the same features as those of the storage-based broadcasting system 100 are not described herein, and only the features unique to the storage-type broadcasting system 1000 is mainly described below.

25 The content assembler 112i has the same functions as those

of the content assembler 112 and also has other functions as follows. That is, the content assembler 112i designates a browser content Cbi among the plurality of content bodies Dc stored in the content body storages 113a, 113b, and 113c. The content
5 assembler 112i then extracts the content ID and the content version of the designated content (browser content Cbi) as browser designation information Bid. The content assembler 112i then outputs the extracted browser designation information Bid to the service property storage 111.

10 Based on the browser designation information Bid, the service property storage 111 writes the content ID and content version of the browser content Cb in the service property information Isp, as shown in FIG. 16. That is, service property information Ispi has a browser content designator composed of the
15 content ID and the content version. One browser content designator is provided for each service. Therefore, the browser content Cb (Cbi) can be discriminated from other contents. As such, the service property information Isp with the content ID and content version of the browser content Cbi written therein
20 is referred to as the service property information Ispi for identification.

Designation of the browser content Cbi is made not by the browser content flag of a content header HcBi, but by the content assembler 112i selecting the content.

25 In FIG. 17, one example of a content header HcBi is shown.

Designation of the browser content Cbi is not made by the browser content flag Bflg. Therefore, the content header HcBi does not include a row for the browser content flag Bflg. Moreover, in the content header, the service content Cs and the browser content Cb cannot be discriminated from each other. In the example shown, a human-readable character string in a "content name" row seems to make it possible to recognize whether the content is the browser content Cb or not. However, in the level of the transmitting apparatus 1010 and the receiving apparatus 130, such recognition cannot be made.

As such, in the storage-based broadcasting system 1000, the receiving apparatus 130 is identical in structure to its counterpart of the storage-based broadcasting system 100, but is slightly different in operation because of different program code and data stored therein.

With reference to a flow chart shown in FIG. 18, the process of activating the browser content Cbi by the receiving apparatus 130 is now described. The process in steps S501i, S502, and S505i is basically the same as that in step S501, S502, and S505 described with reference to FIG. 9 except that the service property information Isp is replaced with the service property information Ispi and that the target content C is replaced with the browser content Cbi. Therefore, description of the above process is not made herein.

In step S1401, by referring to the service property

information Ispi, the browser content designator of the determined service is extracted.

In step S1402, the storage 133 is searched for the content C (browser content Cbi) with the content ID and content version
5 of the browser content designator extracted in step S1401. Then, the found content C is designated as the browser content Cbi.

Designation of the browser content Cbi is carried out by the content assembler 112i. Therefore, if the content assembler 112 is managed properly, redundant designation of the browser
10 content Cbi or erroneous designation of other service content C as the browser content Cbi can be prevented.

As stated above, in this embodiment, the content body pitcher 114 sends the bodies of the browser contents Cbi that each provide a user interface with a service. The service property
15 storage 111 sends, as the browser content designator used for all services in common, the browser designation information Bid for designating the browser content body DCb among a plurality of contents as being included in the service property information Ispi. The receiving apparatus 130 determines, based on the browser
20 content designator, that the content C is the browser content Cbi. With these components provided, the storage-based broadcasting system 100 ensuring discrimination between the browser content Cb and the service content Cs can be achieved.

In other words, in the third embodiment, the browser content
25 Cb is designated by the control content designator used for the

plurality of services in common. Then, the designation information of the browser content Cb is separated from the content and content header. Thus, willful designation of the browser content Cb for another service can be prevented
5 irrespectively of the information stored in the content body storage. For example, the designation information of the browser content Cb may be managed under control of a contract broadcasting company instead of each service provider so as to prevent designation of an authorized browser content Cb among the service
10 providers.

(Fourth embodiment)

With reference to FIGS. 19, 20, 21, 22, and 23, a storage-based broadcasting system according to a fourth embodiment of the present invention is described. As shown in
15 FIG. 19, a storage-based broadcasting system 1500 according to this embodiment includes, a transmitting apparatus 1510, a delivery system 120, and a receiving apparatus 130, as in the storage-based broadcasting system 100 shown in FIG. 1. The transmitting apparatus 1510 is identical in structure to the
20 transmitting apparatus 110 of the storage-based broadcasting system 100 except that a content ID space manager 1581 is additionally provided.

The same features as those in the storage-based broadcasting system 100 are not described herein, and only the
25 features unique to the storage-based broadcasting system 1500 are

described below.

The content ID space manager 1501 manages a range (space) of values that can be taken by the content ID of the content for the service to designate the browser content Cbs.

5 The content ID space is defined in a predetermined manner. For example, the content IDs 100 to 199 indicate the content of the service ID "S1"; 200 to 299 indicate the content of the service ID "S2"; and 300 to 399 indicate the content of the service ID "S3"; and 0 to 99 indicate the browser content Cb (Cbc).

10 The content ID space manager 1501 generates content space definition CSD for outputting to the content assembler 112. Based on the content space definition CSD, the content assembler 112 rewrites the values of the content IDs stored in the content headers Hc (HcBs) for the content bodies Dc (DcBs) provided from
15 the content storages 113a, 113b, and 113c via the content body pitcher 114. Thus, values of the content IDs are replaced with those according to the defined content ID space.

In FIG. 21, one example of the content space definition is shown. The content space definition CSD includes a column for
20 the range of the content ID and information for defining the content space. In this example, contents for the services are created with their content IDs arbitrary set within the range of 0 to 99, and stored in each content body storage. For the service S1, the browser content Cbs generated from the content body Dc
25 provided by the content body storage 113a is outputted if its

content ID is between 0 and 99. At this time, if not between 0 and 99, the browser content Cbs is assumed to be unauthorized, and then excluded.

On the other hand, for the service content Cs for the service
5 S1, 100 is added to the content ID for the conversion thereof within 100 to 199. After conversion, it is checked whether the content ID is within 100 and 199. If within this range, the service content Cs is outputted and, if not, the service content Cs is assumed to be unauthorized, and then excluded.

10 At conversion, the content ID for reference of other content embedded in the content is also converted in a similar manner.

In FIG. 22, the structure of the browser content Cbs replaced by the content ID space manager 1501 is exemplarily shown. In the content header HcBs of the browser content Cbs, the content
15 ID is "001", which is within 0 to 999 defined as the content ID range of the browser content Cb.

The content ID space manager 150⁸1 also adds information for defining the content ID space to the service property information stored in the service property storage 111.

20 In FIG. 20, one example of service property information Isps is shown. The service property information Isps is the same as the service property information Isp according to the first embodiment shown in FIG. 4.

With reference to FIG. 23, the process of activating the
25 browser content Cbs by the receiving apparatus 130 is now

described. The process in steps S501s, S502, S503, and S505s is basically the same as that in steps S501, S502, S503, and S505 described with reference to FIG. 9 except that the service property information Isp is replaced with the service property
5 information Ips and that the target content C is replaced with the browser content Cbs. Therefore, description of the same process is not made herein.

In step S1801, the storage 133 is searched for the content C having the service ID obtained in step S503 and having the content
10 ID within the range of values equal to that of the browser content Cbs designated by the service property information Ips.

In step S505s, the found browser content Cbs is executed.

As stated above, the storage-based broadcasting system 1500 manages the space of the content ID. The content having the
15 content ID of a specific value defined under this management can be designated as the browser content Cbs. As such, without a specific field (column, in this example) provided for the content header HcBs, etc., the browser content Cbs can be designated.

In other words, as long as the content body Dc can be stored
20 in the content storage 113 only by the content provider, the browser content Cb for another service can be prevented from being willfully specified and executed in the receiving apparatus 130.

In the fourth embodiment, if a single content ID space is provided for all service providers, the range of values of the
25 content ID of the browser content Cb is defined in advance. Thus,

willful designation of the browser content Cb among the service providers can be prevented. Only the field of the content ID is used, and a new field is not required to be provided to the content header, etc. Therefore, only a slight modification is required
5 to the conventional transmitting apparatus. Moreover, the content receiving process of the conventional receiving apparatus can be used easily.

While the invention has been described in detail, the foregoing description is in all aspects illustrative and not
10 restrictive. It is understood that numerous other modifications and variations can be devised without departing from the scope of the invention.
